| WHAT IS THE PU | RPOSE HERE? | | | |

- 1. Why do we need data streams?
 - → Historical answer: We need eyes on the scene because adverse Space Weather impacts the crew, primarily Solar Energetic Proton (SEP) events.
 - \rightarrow This answer is not good enough.
 - → Real-time data streams are needed to drive forecasting and maintain situational awareness which, coupled with sheltering-in-place, will minimize dose to the human-vehicle system while optimizing and protecting the operational mission timeline.
 - ightarrow But, should be driven by quantified impact and how the data will be used.
 - → Storm shelter requirements with IPs being developed for Exo-LEO missions. Will protect against 'worst-case' SEPs once on-board instrumentation alerts crew to SEP arrival. Data streams and forecasting will direct storm shelter use and protect critical elements of mission timeline.
- 2. What follows is a quantified impact assessment.

TECHNICAL STRATEGY

| Purpose | Technical Strategy | Results | Conclusion | Backup |
|-----------|--------------------|---------|------------|--------|
| HOW CAN \ | WE ASSESS IMPACT? | | | |

- \rightarrow Largest impact is 'free-space', not on ISS, i.e. missions outside of LEO.
- → Have a wealth of instrument data of radiation dose on ISS, some of this pertains to space weather effects (SEPs).
 - → But, times of adverse space weather impact on ISS is limited to short time frames (upper latitude passes) and thus relatively low cumulative dose.
- $\rightarrow\,$ We have 'free-space' particle fluxes in real-time.
- $\rightarrow\,$ We have 'free-space' particle fluxes over ISS Expedition time frames.
 - $\rightarrow~$ Using these fluxes to model the dose effectively moves ISS to free-space.
- → Model SEP dose on ISS and thinner shielded vehicle models using measured free-space flux and compare with measured ISS SEP dose.
 - → Will yield a quantified impact of cumulative SEP dose for exo-LEO missions relative to missions that have been conducted in LEO under established processes for radiation mission operations.

SEP CHARACTERISTICS DURING EXPEDITION TIME FRAME

- → Number of SEPs per expedition ranges from zero (solar minimum), to 13 for Expedition 2 (near solar maximum for cycle 23). (Total of 133 events.)
- → The 'in-event' time defined as the fraction of cumulative time SEP > 10 MeV fluence was above background levels to the total expedition time.
- → The highest in-event time was 87% -Expedition 3 (mid-2001 to 2002, solar max for cycle 23).
- → Operational impacts increase with increasing in-event time. (Discussed further in following charts.)

| Purpose | Technical Strategy | Results | Conclusion | Backup |
|---------|--------------------|---------|------------|--------|
| o | 0000 | 0000000 | O | 0000 |
| | | | | |

- → To assist in understanding SEP dose relative to 30-day thresholds one can look at duration.
- → Well-known that time profile varies with proton energy.
- → Calculate event duration only for events that have non-zero fluence at a given energy above a threshold value.
- → Going to higher threshold corresponds to filtering out less energetic (and often less intense) events.
 - → As a result the average duration increases.
- → All long-duration events are typically also energetic events.

| Purpose | Technical Strategy | Results | Conclusion | Backup |
|-----------|---------------------|---------|------------|--------|
| o | 000● | 0000000 | O | 0000 |
| COMPARISO | N WITH 30-DAY LIMIT | | | |

- → Two over-arching risk-mitigation perspectives for Ops: (1) ALARA (2) NCRP 30-Day limits (distinct for skin, eye and BFO).
- → Calculations here are point doses. Although they don't take into account body self-shielding explicitly, self-shielding represents only about 5 g/cm² of additional shielding thickness.
 - \rightarrow Small contribution for thickly-shielded vehicles (ISS, DSH, SM).
 - → Larger effect for thinly-shielded vehicles (CEV). However, 70% of CEV vehicle thickness is greater than 5 g/cm².
 - $\rightarrow~$ To compare directly to ISS instrument response, self-shielding is not included.
- → To assess a mission greater than 30 days in duration and compare to 30-day limit we have to assess the contribution from individual SEP events.
 - $\rightarrow~$ All SEP events over ISS Expedition time frame (2000-2012) are $\lesssim 30$ days.

| | | | | |

INDIVIDUAL EVENT DOSE: EXPEDITION 1

 \rightarrow Large dispersion in event dose.

→ Ratio of CEV to USLAB dose relatively constant.

→ Largest doses correspond to large-fluence events with durations on the order of weeks to one month.

INDIVIDUAL EVENT DOSE: EXPEDITIONS 4 AND 5

11

| 0 | 0000 | 000000 | 0 | 0000 |
| | | | | |
| COMDADISC | | DEMENITS ON ISS IN | | |

- → Use ISS measurements in LEO (via TEPC instrument) to compare to 'free-space' modeling with US LAB.
- → Yields an estimate of SEP event instrument response for scenarios such as transit to Mars.
- → Expeditions 4, 10 and 11 have the highest estimated ratios of free-space to LEO TEPC response.
- → Ratio is relative and depends on how well ISS was 'phased' with high latitude regions.
 - → Represents a lower bound. Could be much larger response with thinly-shielded vehicle.

- → In-event time corresponds to time that SEP impact is part of operational decision tree.
- $\rightarrow~18\%$ on average with a standard deviation of 22%.
- → However, there were 5 Expeditions where more than half of the mission time was impacted by having to react in real-time to SEP events.
- → This is particularly disrupting to operational activities that are time critical.

| Purpose | Technical Strategy | Results | Conclusion | Backup |
|----------------|----------------------|---------|------------|--------|
| o | 0000 | 0000000 | O | 0000 |
| OPERATIONAL TI | MELINE IMPACTS: PART | 2 | | |

- → For lower doses (<10 cSv) cumulative dose equivalent increases with in-event time.</p>
- → Largest cumulative dose equivalent calculated correspondeds to almost a 116-day mission where the proton flux was elevated almost more than 80% of the mission - large operational impact.
- → Without a storm shelter and operational strategies for using it (data streams and subsequent forecasting capability) may be challenging to maintain ALARA and 30-day limit over a wide range of in-event times (10% to > 80%).
- → Now couple this with how dose trend correlates with mean-event time (next slide).

| Purpose | Technical Strategy | Results | Conclusion | Backup |
|----------------|----------------------|---------|------------|--------|
| o | 0000 | 000000 | O | 0000 |
| OPERATIONAL TI | MELINE IMPACTS: PART | 3 | | |

- → Mean event time is average event duration over a single Expedition.
- → Expeditions with large doses correspond to mean event durations ranging from roughly 1 to 3 weeks.
- → Take home here is that although the largest doses over an expedition correspond to time windows on the order of 30-days, the multitude of periods of elevated flux over any given Expedition, without the capability to forecast duration, peak flux, etc, can lead to 'reacting' to these conditions over a relatively large fraction of the entire mission duration.

CONCLUSION

| Purpose | Technical Strategy | Results | Conclusion | Backup |
|--------------|--------------------|---------|------------|--------|
| o | 0000 | 0000000 | • | 0000 |
| CONCI USIONS | | | | |

- → Appears that single large episodes dominate the expedition dose and each falls within a 30-day window.
- → Fraction of mission time responding to elevated flux over the course of any single expedition can be quite large (see as high as 87%). Forecasting capability needed.
- → SEP dose equivalent results indicate ISS instrument response would be a minimum of a factor of 40 times greater if ISS was located in free-space than in LEO.
- → All results indicate SEP events can have a large impact on operations for missions beyond LEO. Real-time data relevant to forecasting model input is needed to mitigate operational impacts and optimize storm shelter use to minimize exposure and increase number of mission-safe days.
- → Moreover, we can't focus just on the human but rather the human-vehicle system. Forecasting capability is needed for informing flight control teams when to power down critical systems.
- → Forecasting SEP onset, peak flux and time profile on a 24-hour to 72-hour window needed to mitigate operational impacts.

CUMULATIVE DIFFERENTIAL FLUENCE INPUT SPECTRA

- → Cumulative differential fluence spectra fit with various functional forms.
 - \rightarrow Power-law
 - → Weibull
 - → Ellison-Ramaty
 - → Band
- → Choose function that yields the lowest χ^2 .
